

Project For Newbieron Technologies

Name of project : - Statewise production of crop in India

Steps for the project

- 1. Data Scrapping**
- 2. Data Cleaning**
- 3. Data modelling**
- 4. Data Visualization through Python**
- 5. Data Visualization through Tableau**
- 6. Dashboard**
- 7. Conclusion**

About the topic

Statewise Production of crop in India.

It is basically about the comparison of states of production of its crop in India with its comparison with its area too. As we all know, India is having different weather conditions in different states for e.g. Jammu and Kashmir is having cold weather and Tamil Nadu is mostly hot while the north east is having most of the monsoon. Also, India is having different tropical condition which also affect the crop production for e.g. Uttarakhand and Himachal Pradesh are having mountainous region while Uttar Pradesh is having plains region. Also, western ghats and eastern ghats are mostly tropical region and having different weather type and hence eventually affect the production of crops.

Hence, in this topic, we have to visualize the data that how different crops are being produced in different states in India and also, which types of crop are mostly produced while which crops are least produced in India.

Data Scrapping

I have searched all over the internet to get the data and finally found kaggle websites the best to provide me the required data. It is very easy to download the required data and the following data was downloaded in excel format.

The excel data was having 8 columns and 246090 rows . The columns were namely Index, state_name, District name, crop , crop year , season , area and production.

The data shows production of crop with states as well as district wise. The data also shows different season as well as area of different states and crops.

Data cleaning

First , I have opened my Jupyter note and upload the data in csv format and then uploading the data in python workbook to read the data. I have imported required libraries such as Pandas , numpy and matplotlib . Pandas is used to read the data while matplotlib is used to visualize data.

First , I have used head command to see the required data and found that index column to be the useless one so I have dropped the index column. Then , I have checked its shape and data type to execute the data. Then I have checked that is there

any missing value in the data which might change the data and found that there are some missing value in the data and then I have cleaned the data and hence checked again to as to confirm there is no missing data left.

Data Modelling

Data modeling is the process of creating a visual representation of either a whole information system or parts of it to communicate connections between data points and structures. In this , I have checked that how data is related to each other so as to analyse the data at its best and get the conclusion.

I have found that the state are related to district and its area and production of crops. As well as there is another data which tells about the different season with crop type and production.

Hence we found that there can be four relation which can setup i.e. state name and crop production, state name and area, season and production of crop and statewise and crop wise production.

Data Visualization with python

After cleaning and modeling the data , we have to visualize the data that so as to get the best insights from the data . In this , we have used matplotlib pyplot library to make the required the charts of above mentioned graphs.

In this bar charts , we got the relationship between statewise production of crops, states with its area in descending order and season with the production of crops.

Data Visualization with Tableau

The data is then transferred to tableau to get the best visualization. In this we have first uploaded the data in tableau and then make the bar charts of Statewise production of crops in India , state with its area, season and production of crops in India and crop and its production.

I have make another sheet in which I have club the state and crops with its production. I have used dropdown options so as to visualize the data i.e. we can select the select the state and see the production of different crops in that particular state for e.g. we have select Uttar Pradesh as a

state and visualize the production of different crops . We got to know that sugarcane is produced most in uttar pradesh.

Also, we can visualize the crops and its production in different states for e.g. we have select bajra as a crop and visualize its production in different states and we got to know that Bajra is mostly produced in Rajasthan following with Uttar Pradesh.

Dashboard

After visualizing different bar charts of different relation , I have then merged the the following sheets to get the dashboard so as to visualize the whole data in one single sheet .

Conclusion

In this following project, we can conclude that the production of crops varies differently in India . Different states have different climate to produce the different crops.

After visualization , we found that coconut is produced mostly In India following with sugarcane and rice while production of bitter gourd , turnip is least. Also , production of ash gourd , beet root is nil .

Analyzing the states, we conclude that Kerala is best state in production of crops following with Andhra Pradesh and Tamil Nadu while Chandigarh and Mizoram has least production.

If we talk about area then we can say that Uttar Pradesh has the largest area following with Madhya Pradesh and Maharashtra while Chandigarh has the least area.

If we analyze the season then the crops produced in whole year has the best largest production following with Kharif and rabi crops while crops are least produced in Autumn season.
